American Heart Association | American Stroke Association
life is why

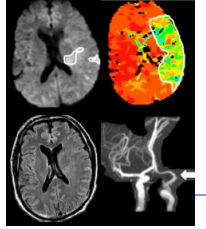
In patients eligible for IV alteplase, benefit of therapy is time dependent, and treatment should be initiated as quickly as possible.

I



Fibrinolyse cérébrale:
En pratique

Indications (SFNV):

Déficit neurologique brutal et focal révélant un infarctus cérébral,

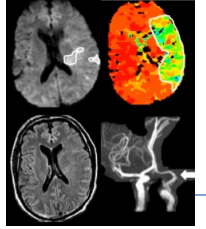
Heure de début des signes <4H30,

Possibilité d'injecter le rt-PA dans les 4H30,

Imagerie validée (IRM ou TDM).

HAS
HAUTE AUTORITÉ DE SANTÉ

La thrombolyse IV peut être envisagée après 80 ans jusqu'à 3 heures (accord professionnel).



Fibrinolyse cérébrale:
Quelle imagerie initiale

RECOMMANDATIONS DE BONNE PRATIQUE

HAS

Accident vasculaire cérébral : prise en charge précoce (alerte, phase préhospitalière, phase hospitalière initiale, indications de la thrombolyse)

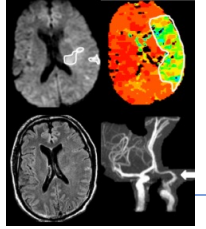
Mai 2009

Les patients suspects d'AVC aigu doivent avoir un accès prioritaire 24 h/24 et 7 j/7 à l'imagerie cérébrale. Des protocoles de prise en charge des patients suspects d'AVC aigu doivent être formalisés et contractualisés entre le service accueillant ces patients et le service de radiologie (accord professionnel).

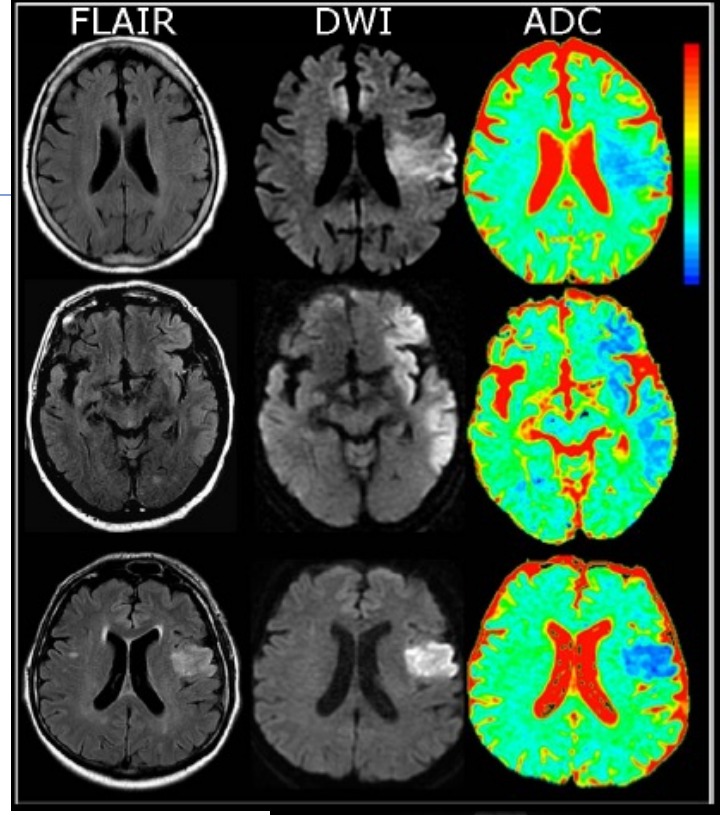
L'IRM est l'examen le plus performant pour montrer précocement des signes d'ischémie recente, et elle visualise l'hemorragie intracrânienne. Il convient de la réaliser de façon privilégiée.

Si l'IRM est possible comme examen de première intention, elle doit être accessible en urgence et elle doit privilégier des protocoles courts incluant les séquences suivantes : diffusion, FLAIR, écho de gradient (grade B).

En cas d'impossibilité d'accéder en urgence à l'IRM, il convient de réaliser un scanner cérébral. Cet examen ne montre qu'inconstamment des signes d'ischémie récente, mais permet de visualiser une hémorragie intracrânienne.

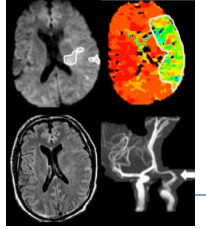


Fibrinolyse cérébrale:
Quelle imagerie initiale



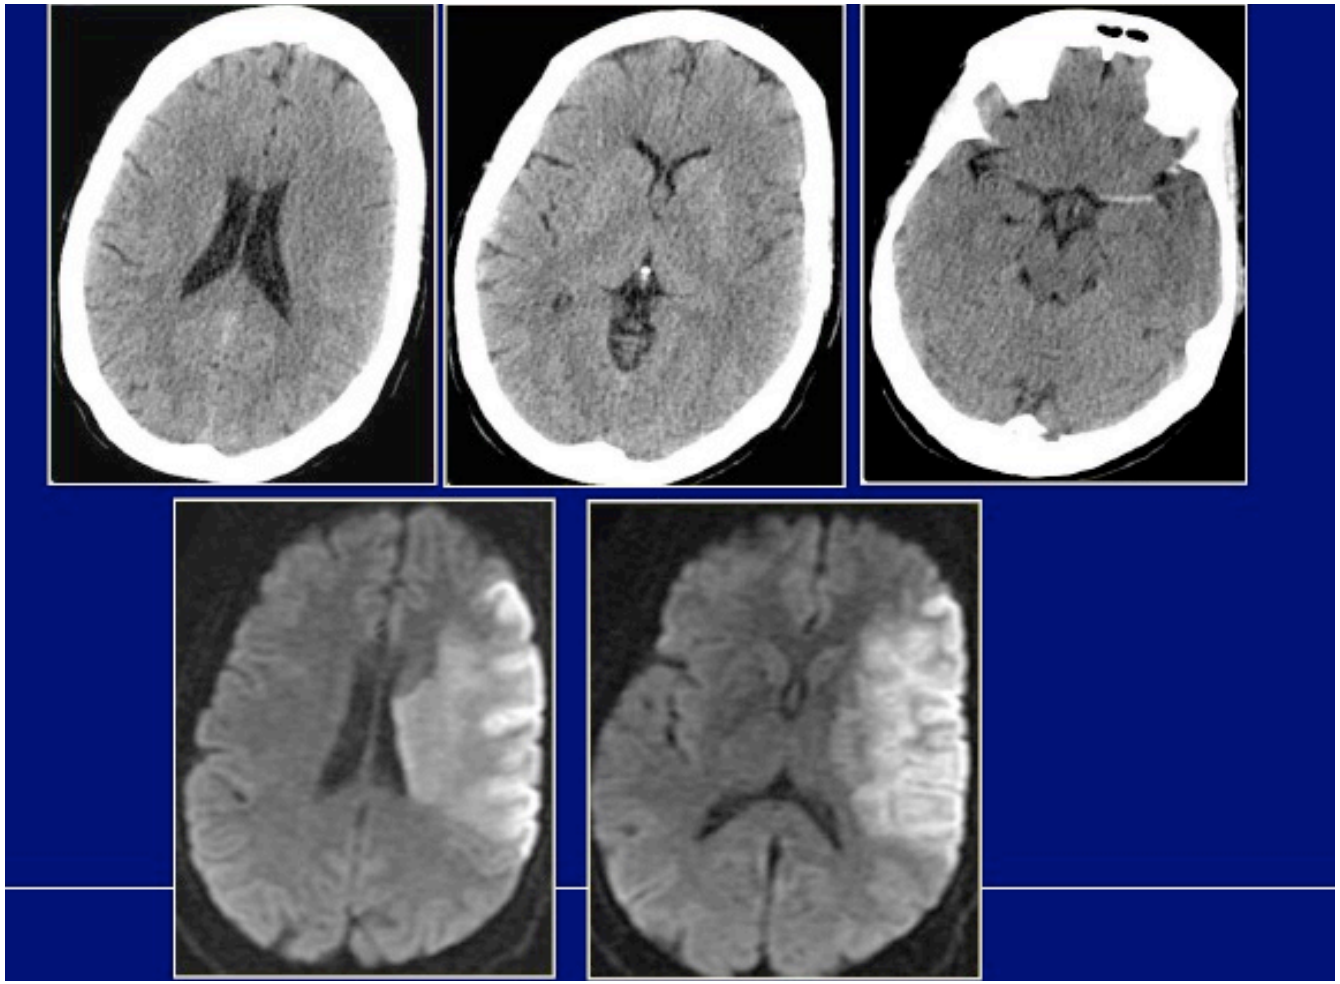
Fibrinolyse en IRM:

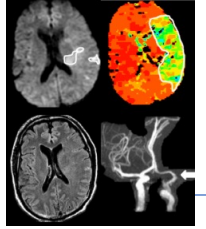
- **Avantages**
  - ✓ Certitude diagnostique
  - ✓ Etendue précise des lésions
  - ✓ Visualisation de l'occlusion artérielle
  - ✓ Visualisation de la « pénombre » ischémique
- **Inconvénients**
  - ✓ Temps d'acquisition plus long
  - ✓ Impossible chez certains patients
  - ✓ Pas de critères validés pour les contre-indications
  - ✓ Peut compliquer la décision (microsaignements, lésion étendue en diffusion, absence d'occlusion...)



Fibrinolyse cérébrale:
Quelle imagerie initiale

Fibrinolyse en IRM: Intérêt pour le diagnostic positif de l'AVCI





Fibrinolyse cérébrale:
En pratique

Contre-indications (SFNV):

- Le scanner ou l'IRM montre une hémorragie ou un effet de masse (secondaire à une tumeur, une malformation artérioveineuse ou autre)
- Traitement anticoagulant oral en cours ou INR > 1,7
- Un traitement par héparine (ou HBPM à dose efficace) a été administré au cours des 48 heures précédant l'accident ischémique cérébral et le TCA (ou l'activité anti-Xa) est allongé.
- Taux des plaquettes < 100 000/mm^3
- Autre AVC ou tout traumatisme crânien sévère dans les 3 mois précédents
- Pression artérielle systolique > 185 mmHg ou pression artérielle diastolique > 110 mmHg au moment de l'administration du rt-PA
- Déficit neurologique en voie de régression
- Déficit neurologique mineur (NIHSS < 4, tel que déficit sensitif isolé, dysarthrie isolée ou déficit moteur minime)
- Antécédents d'hémorragie intracrânienne, de malformation artérioveineuse ou d'anévrisme intracérébral
- Le patient présente un syndrome méningé (même si le scanner cérébral est normal)
- Glycémie < 0,5 g/L ou > 4 g/L
- Crise d'épilepsie lors de l'installation de l'accident ischémique cérébral*
- Intervention chirurgicale majeure < 14 jours
- Infarctus du myocarde récent (moins de 3 semaines)
- Ponction lombaire ou ponction récente d'un vaisseau non compressible (moins d'une semaine)
- Score du NIHSS > 25 ou coma profond, avec déviation forcée des yeux et hémiplégie complète
- Le scanner ou l'IRM cérébrale montre des signes étendus d'ischémie (atténuation de densité ou effet de masse > 1/3 du territoire de l'artère cérébrale moyenne)
- Endocardite infectieuse
- Antécédents de péricardite datant de moins de 3 mois
- Refus du patient et de sa famille
- Femmes enceintes ou en *post-partum* < 14 jours
- Handicap neurologique préexistant (dépendant, non ambulatoire)
- Le patient présente une dissection intracrânienne
- Le rapport bénéfice-risque du rt-PA doit être soigneusement évalué chez les patients de plus de 80 ans

Evaluation de la pénombre ischémique

AVCI associé à une occlusion de la CI intracrânienne et/ou du segment M1 de l'ACM

DAWN Vs. DEFUSE3 Key Inclusion and population Differences		
	DAWN	***DEFUSE-3***
enrollment NIHSS	>10	>=6
Age	>18	18-90
Infarct Size	Stratified, max 51ml	<70 ml
Imaging Inclusion	Mismatch between severity clinical deficit and infarct volume	Ischemia to penumbra ratio
Time inclusion (hrs post last seen normal)	6-24	6-16

DAWN TRIAL

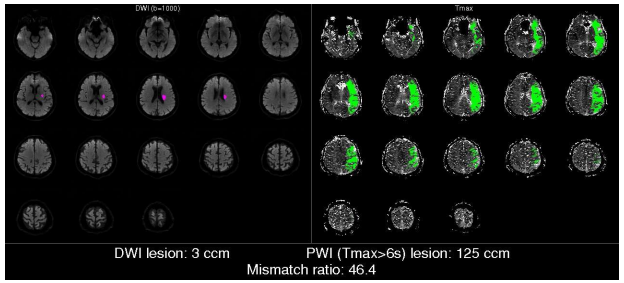
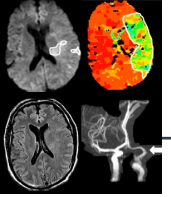
Mismatch clinico-radiologique:

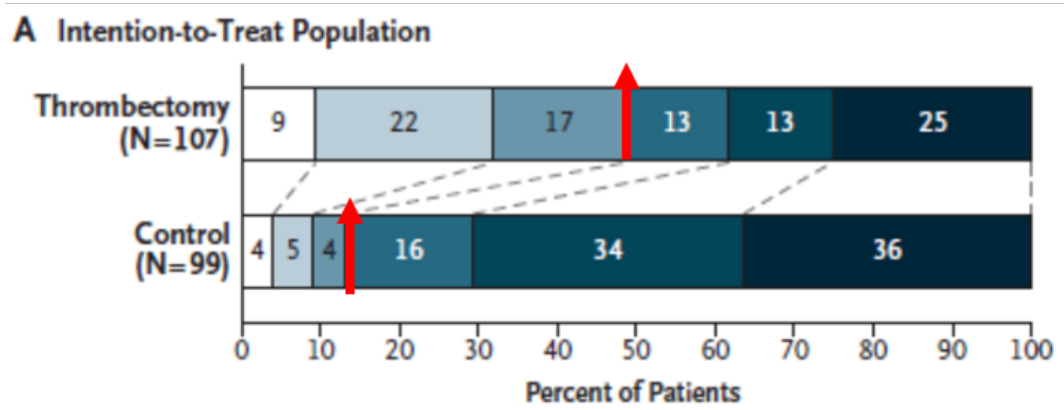
80 ans ou plus; NIHSS> ou égal à 10; DWI < 21 ml
< 80 ans; NIHSS > ou égale à 10; DWI < 31 ml
< 80 ans; NIHSS > 20 ou égal à 20; DWI entre 31 et 51 ml

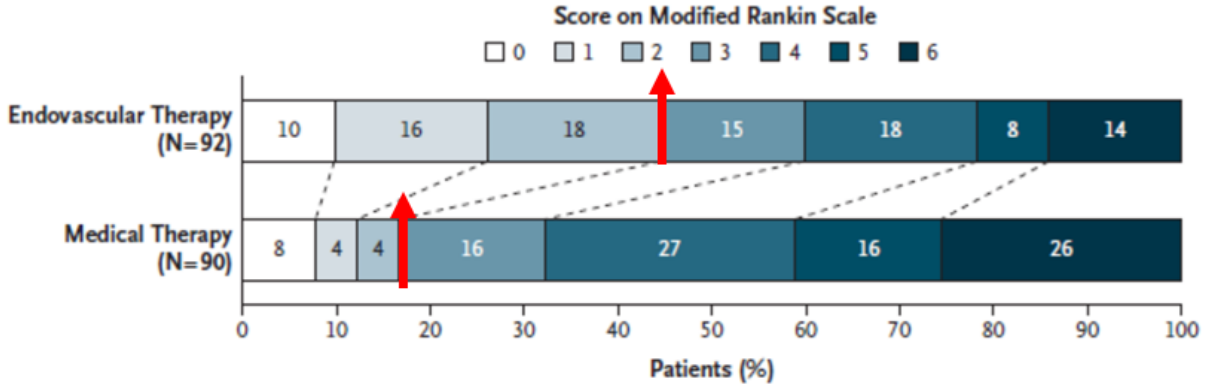
Mismatch radiologique:





La thrombectomie tardive (Etudes DAWN et Defuse 3)





American Heart Association | American Stroke Association
life is why

7. In selected patients with AIS within 6 to 16 hours of last known normal who have LVO in the anterior circulation and meet other DAWN or DEFUSE 3 eligibility criteria, mechanical thrombectomy is recommended.	I	
8. In selected patients with AIS within 16 to 24 hours of last known normal who have LVO in the anterior circulation and meet other DAWN eligibility criteria, mechanical thrombectomy is reasonable.		IIa

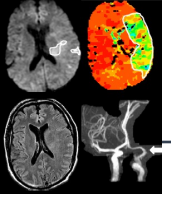
Stroke

In summary, our analysis demonstrates that application of the DAWN and DEFUSE-3 enrollment criteria to an AIS population would impact 1.7% to 2.7% of total patients presenting to a comprehensive stroke center. These data have important implications for an anticipated rise in the number of thrombectomy-eligible patients and increased resource needs.



Take Home Message

- **La TM complète la thrombolyse IV dans les occlusions proximales de la circulation antérieure *(Imagerie vasculaire; Règle des 6)***
- **Pour les AVCI sans occlusion proximale, la thrombolyse IV reste le gold-standard (≤ 4h30)**
- **La thrombolyse IV peut être considérée pour les AVCi du réveil sur la base d'une sélection par IRM**
- **En cas d'occlusion proximale, la TM peut-être envisagée de 6 à 24 heures en fonction de l'évaluation de la pénombre ischémique**
